Background	apoptotic peptidase activating factor 1(APAF1) Homo sapiens This gene encodes a cytoplasmic protein that initiates apoptosis. This protein contains several copies of the WD-40 domain, a caspase recruitment domain (CARD), and an ATPase domain (NB-ARC). Upon binding cytochrome c and dATP, this protein forms an oligomeric apoptosome. The apoptosome binds and cleaves caspase 9 preproprotein, releasing its mature, activated form. Activated caspase 9 stimulates the subsequent caspase cascade that commits the cell to apoptosis. Alternative splicing results in several transcript variants encoding different isoforms. Other	APAF1, Apoptotic protease-activating factor 1; APIP2; CGI-29 protein; MMRP19; dJ179L10.2; likely ortholog of mouse monocyte macrophage 19
